Studies on Creating Cold Resistant *Trachycarpus fortunei* in Beijing

**Chen, R.; Chen, J.**

College of Landscape Architecture, P.O. Box 113, Beijing Forestry University, 100081, Beijing, China

*Trachycarpus fortunei* is not only an important plant material in forestry and urban Landscape, but also one of the most cold hardy species in *Trachycarpus* genus. It could resist -7.1 °C in the open in Sihuiuan Province. The distribution of *T. fortunei* is mainly along Qinling, to Yangzi River area. There was no record for cultivation of this species in Beijing before 1979. The seedlings in Beijing were from the seeds in Xi’an and sowed in 1980. They could resist -17.8 °C for a short period. In January 2009, the lowest temperature had reached -16 °C. The temperature is almost the lowest in the past 40 years in Beijing in December. The 30-year-old *Trachycarpus* only have freezing injury on old leaves. Electrical conductivity test of different *T. fortunei* for different regions was conducted. The result showed that the leaves of *T. fortunei* in Beijing is more cold resistant than the same species in Kunming, Yunnan Province. The *T. fortunei* tree bore fruits every year after 2005. Over 8622 seeds were obtained in December 2009. The result showed that it was a successful way to create the cold hardy *T. fortunei* for acclimatization. *Rosa damascena* Mill. is mainly used for essential oil production. Due to the low oil content in *Rosa* genus, its medicinal properties and the lack of natural and synthetic substitutes, rose oil is one of the most expensive essential oils in the world markets. Nine polymorphic microsatellite markers were used to analyze the genetic diversity of 40 accessions of *R. damascena* collected across major and minor rose oil production areas in Iran. Along with several morphological characteristics, the oil content and composition of the mentioned plant material were measured for two years. In order to discover any possible association between molecular markers with some morphological traits or essential oil components stepwise regression analyses were performed. All microsatellite markers showed a high level of polymorphism (5–15 alleles per microsatellite marker, with an average of 9.11 alleles per locus). Furthermore, the morphological and phytochemical analyses demonstrated the similar level of polymorphism. Some traits such as the number of petals, stamens and flower weight showed 88.2, 71.7 and 84 percent association with the molecular data, respectively. Moreover, a number of essential oil components such as Geraniol, Citronellol, β-Bourbonene, Hexadecanal and Heptadecane showed low or moderate levels of association with microsatellite markers.

To investigate the effect of various preservative solutions on the postharvest characteristics of cut rose (*Rosa hybrida L. cv. Grand Prix*), the experiment was done in the frame of completely randomized design with 3 replicates. Cut roses were continuously treated with distilled water (as control) and solutions containing silver thiosulphate, sodium nitroprusside, ethanol, thyme oil, hydrousquino-line sulphate. Sucrose was used in all of treatments except control solution. During postharvest life of flower, parameters comprising of vase life, flower diameter, bud opening stages, bent neck, display quality, water uptake, fresh weight, dry weight and chlorophyll and carotenoid were measured. The results indicated that all used treatments in this study, except treatment of 10 % ethanol plus 15 % sucrose resulted to extend the vase life which between these treatments, 400 mg/l HQS plus 15 % sucrose prolonged the longevity, higher than the other treatments. Besides, it was observed that flower diameter in all of vase solutions was increased until fourth day, but after this day was decreased. However, effect of 10 % ethanol and 2 ml/l essential oil treatments on the enhancement of flower diameter was lower than control and other treatments. Theses later solutions markedly was resulted to decline flower opening, whereas the other treatments didn’t. After 6 days of treatments, 50 μM SNP-treated flowers maintained water uptake more effectively than did controls or flowers treated with other solutions. Six days being treated with preservative solution containing 400 mg/l HQS resulted to obtain the highest fresh weight than others. Also, dry weight of cut roses that kept in 400 mg/l HQS plus 15 % sucrose solution were estimated higher than ones.
